#### Abstract

Based on the logistics nodes system consisting of first-degree logistics node (logistics park) secondary logistics nodes (including logistics center and distribution center), a dynamic logistics nodes location model of multi-period , multi-type cargo flow and multiple logistics nodes is given. The optimization model considers the factors including fixed cost for logistics opening, handling cost and economic of scale of different type logistics nodes. An effective algorithm based on the improved minimum cost-maximal flow algorithm and genetic algorithm is presented according to the characteristic of optimization problem. Finally, a numerical example is provided to validate the proposed model and solution algorithm. The findings indicate that the model proposed in this paper is a useful tool for the investigation of the Multi-period and Multiple Logistics Node Dynamic Location Problem.

Keywords: Logistics nodes, System layout, Optimization model, Heuristic rules, Hybrid genetic algorithm

## 1. Introduction

The logistics network design of a city is very important to reduce the social distribution costs and improve the efficiency of distribution. The literature on the city logistics network design problem is extensive with a wide variety of solution methods. Ballou (1968) was the first to address the dynamic location problem and suggested a heuristic algorithm for its solution. Geoffrion and Graves (1974) provided a solution procedure based on Bender's decomposition and applied it to a real situation for a major food company. Denis (1976) investigated the multi-commodity and multi-period e facility location problem, and gave the heuristics algorithm based on dynamic programming. Alexander (1991) studied the multi-period and multi-stages location problem, and solves the model by the Lagrangian heuristics combined with dynamic programming. John (1997) proposed a dynamic location model with uncertain quantity facilities by applying the heuristics based on decision criteria: the minimization of expected opportunity loss and the minimization of maximum regret. Nozick (2001) presents a combined location model considering facility costs, inventory costs, transportation costs, and customer's responsiveness. A comprehensive review on the facility location model can be found in Andreas Klose et al. (2005).
In this paper, we present an optimization model to solve the capacitated, multi-commodity, multi-period, multi-class logistics node location problem. And an effective algorithm is given which is based on hybrid algorithm and heuristic rules.
The rest of this paper is organized as follows. In Section 2 we present an optimal mathematical model of the capacitated, multi-stage, multi-commodity dynamic logistics nodes location problem. Section 3 provides the development of the algorithm for solving this problem. The fourth section presents an illustrated application, while the last section presents conclusions and suggestions for further research.

## 2. Model formulation

In this paper, we consider a city long-term logistics nodes system planning according to its logistics need changes in the future 2 years. The logistics nodes systems planning consists of three stages, taking from 1 to 5 as stage 1 , from 5 to 10 as stage 2 , and from 10 to 20 as stage 3 . The logistics nodes are made up of the first class logistics nodes and the second class logistics nodes. The first class logistics nodes have the logistics hub function, such as Logistics Park. While the second class logistics nodes have the distribution function, such as Logistics Center and Distribution Centers. We denote the first class logistics nodes as LN (I), the second logistics nodes as LN (II). The planning aim is to enhance distribution efficiency and cut down the society logistics cost by optimizing the layout logistics nodes step by step.
The assumptions to the model are as follows.
(1) There are $n 1$ candidate locations of $\mathrm{LN}(\mathrm{I}), \mathrm{n} 2$ candidate locations of $\mathrm{LN}(\mathrm{II})$ and m customer demand spots, where LN(I), LN(II) represents the first class logistics nodes.
(2) The candidate logistics nodes are satisfied on traffic conditions and others necessary location conditions.
(3) The design parameters and relative construction cost of each potential logistics nodes are known in advance.
(4) The transportation costs among LN (I) nodes, LN (II) nodes and customers are given.
(5) The demand of customer zones is obtained in advance.

## Inputs and Sets

$I$ : set of the candidate locations of first class logistics nodes, indexed by $i$
$J$ : set of the candidate locations of second class logistics nodes, indexed by $j$
$N$ : set of customer locations, indexed by $n$
M: set of the commodities, indexed by $m$
$T$ : set of the planning time, indexed by $t$
$F_{k}(t)$ : the fixed cost of operating logistics nodes $k$ in time $t ; k \in I \cup J$
$C_{i j}^{m}(t)$ : the unit shipment cost of commodity $m$ from $\mathrm{LN}(\mathrm{I}) i$ to $\mathrm{LN}(\mathrm{II}) j$ in period $t$
$C_{j n}^{m}(t)$ : the unit shipment cost of commodity $m$ from $\mathrm{LN}(\mathrm{II}) j$ to customer $n$ in period $t$
$C_{k}^{e}(t)$ : the expanding cost of logistics nodes $k$ in time $t ; k \in I \cup J$
$U 1_{i}(t)$ : the initialization design capacity of $\mathrm{LN}(\mathrm{I}) i$ for commodity $m$ in time $t, i \in I$
$U 2_{j}(t)$ : the initialization design capacity of $\mathrm{LN}(\mathrm{II}) j$ in time $t, \quad j \in J$
$U_{i}^{\text {max }}(t)$ : the maximal capacity of $\mathrm{LN}(\mathrm{I}) i$ by expanding in time $t, i \in I$
$U_{j}^{\max }(t)$ : the maximal capacity of $\mathrm{LN}(\mathrm{II}) j$ by expanding in time $t, j \in J$
$D_{n}^{m}(t)$ : the demand of customer $n$ for commodity $m$ in time $t$,
$\varphi_{i}^{1}(t), \varphi_{j}^{2}(t)$ : the unit cost of process of $\mathrm{LN}(\mathrm{I}) i$ and $\mathrm{LN}(\mathrm{II}) j$ in time t respectively.
$\theta_{i}^{1}(t), \theta_{j}^{2}(t)$ :the relative agglomeration factors in $\mathrm{LN}(\mathrm{I}) i$ and $\mathrm{LN}(\mathrm{II}) j$ in time t respectively.
(generally speaking, $0 \leq \theta_{i}^{1}(t) \leq \theta_{j}^{t}(t) \leq 1$, and the less the value of agglomeration factors, the more the benefit of scale economy )
$R_{i}^{1}(t), R_{j}^{2}(t)$ : the total shipment of $\mathrm{LN}(\mathrm{I}) i$ and $\mathrm{LN}(\mathrm{II}) j$ in time t respectively, $i \in I, j \in J$
$a_{i}^{t}, b_{j}^{t}$ : the expanding cost of $\mathrm{LN}(\mathrm{I}) i$ and $\mathrm{LN}(\mathrm{II}) j$ in time t respectively, $i \in I, \quad j \in J$
$A_{k}(t)$ : the equal instalment system
$A_{k}(t)=F_{k} \frac{r(1+r)^{N_{k}^{0}}}{(1+r)^{N_{k}^{0}}-1} \quad \forall t \leq n_{k}^{0} \quad A_{k}(t)=0 \quad \forall t>n_{k}^{0} \quad$ where, $n_{k}^{0}$ : the investment recovery period
of logistics node $\mathrm{k} ; r$ : the capital discount rate;
$S_{k}^{t}$ : the salvage value of the closed logistics nodes k in time $\mathrm{t} S_{k}^{t}=\sum_{\tau=1}^{N_{k}-t} A_{k}(1+r)^{-\tau}$
$\operatorname{Dec}(f)$ : sign function, if $\mathrm{f}>0, \operatorname{Dec}(\mathrm{f})=1$, otherwise $\operatorname{Dec}(\mathrm{f})=0$;

## Decision variables:

$X_{i j}^{m}(t)$ : the quantity of commodity $m$ shipped from $\mathrm{LN}(\mathrm{I}) i$ to $\mathrm{LN}(\mathrm{II}) j$ in time $t$
$X_{j n}^{m}(t)$ : the quantity of commodity $m$ shipped from $\mathrm{LN}(\mathrm{II}) j$ to customer $n$ in time $t, Y_{k}(t)$ :the indicator variable for logistics node $k$ building status ( $0=$ closed, $1=$ open)
$E_{k}(t)$ : the indicator variable for logistics node $k$ expanding status ( $0=$ closed, $1=$ open $)$
The capacitated, multi-stage, multi-commodity, dynamic logistics nodes location problem (CMDLNLP) can be formulated as follows:

$$
\begin{equation*}
\operatorname{Min} \quad N P V(X, Y, E)=\sum_{t \in T}\left\{[T C(X, Y, t)+O C(X, Y, t)+A C(X, Y, t)]^{*}(1+r)^{-(t-1)}\right\} \tag{1}
\end{equation*}
$$

where

$$
\begin{aligned}
& T C(X, Y)=\sum_{m \in M}\left(\sum_{i \in I} \sum_{j \in J} C_{i j}^{m} X_{i j}^{m}(t)+\sum_{j \in J} \sum_{n \in N} C_{j n}^{m}(t)\left(X_{j n}^{m}(t)\right)\right. \\
& O C(X, Y)=\sum_{i \in I} \varphi_{i}^{1}\left(R_{i}^{1}(t)\right)^{\theta_{i}^{1}(t)}+\sum_{j \in J} \varphi_{j}^{2}(t) R_{j}^{2}(t)^{\theta_{j}^{2}(t)}+\sum_{t \in T} \sum_{k \in I \cup J} A_{k}(t) Y_{k}(t) \operatorname{Dec}\left(t-n_{k}^{0}\right) \\
& A C(Y, K)=\sum_{i \in I} a_{i}^{t} K_{i}(t)+\sum_{j \in J} b_{j}^{t} K_{j}(t)-\sum_{k \in I \cup J} S_{k}^{t}\left(\left(Y_{k}(t-1)-Y_{k}(t)\right)\right.
\end{aligned}
$$

subject to

$$
\begin{gather*}
\sum_{m \in M} \sum_{j \in J} X_{i j}^{m}(t) \leq U_{i}^{\max }(t) \quad \forall i \in I, t \in T  \tag{2}\\
\sum_{m \in M} \sum_{n \in N} X_{j n}^{m}(t) \leq U_{j}^{\max }(t) \quad \forall j \in J, t \in T  \tag{3}\\
\sum_{i \in I} X_{i j}^{m}(t)=\sum_{n \in N} X_{j n}^{m}(t) \quad \forall j \in J, m \in M, t \in T  \tag{4}\\
\sum_{j \in J} X_{j n}^{m}(t)=D_{n}^{m}(t) \quad \forall n \in N, m \in M, t \in T  \tag{5}\\
\sum_{m \in M} \sum_{j \in J} X_{i j}^{m}(t)=R_{i}^{1}(t) \quad \forall i \in I, t \in T  \tag{6}\\
\sum_{m \in M n \in N} \sum_{j n}^{m}(t)=R_{j}^{2}(t) \quad \forall j \in J, t \in T  \tag{7}\\
E_{i}(t)=D e c\left(R_{i}^{1}(t)-U 1_{i}(t)\right) \quad \forall i \in I, t \in T  \tag{8}\\
E_{j}(t)=D e c\left(R_{j}^{2}(t)-U 2,(t)\right) \quad \forall j \in J, t \in T  \tag{9}\\
X_{i j}^{m}(t) \geq 0 \quad \forall i \in I, j \in J, m \in M, t \in T  \tag{10}\\
X_{i n}^{m}(t) \geq 0 \quad \forall i \in I, n \in N, m \in M, t \in T  \tag{11}\\
X_{j n}^{m}(t) \geq 0 \quad \forall j \in J, n \in N, m \in M, t \in T  \tag{12}\\
Y_{k}(t)=\{0, l\} \quad \forall k \in I \cup J, t \in T \tag{13}
\end{gather*}
$$

In the above formulation, the objective function involves three types of costs: transport costs, handle and fixed costs, and the transitional costs related to the dynamic nature of the problem. It aims to minimize the sum of the costs including: the costs of transport commodity from LN (I) to LN (II) and from LN (II) to customer; the fixed cost associated with locating and operating logistics nodes; the transitional costs of logistics nodes due to expanding and closing.
Constraint set (2) stipulates that all shipments from LN (I) to LN (II) must not exceed its capacity. The capacity restriction of LN (II) is ensured by constraint set (3). Constraint set (4) indicates a conservation of flow at each logistics node, while (5) requires that all customer demands must be met. Constraint sets (6), (7) indicate that the total shipment processed by LN (I) nodes and LN (II) nodes respectively. Constraint set (8), (9) imply the LN (I) nodes and LN (II) nodes to be expanded or not respectively. The non-negativity on each shipment is imposed by constraint sets (10)-(12). Constraint set (13) on $Y_{k}(t)$ restricts every logistics node to be either open or closed.

## 3. Solution algorithm

The above model is a nonlinear optimization model extended from the static location problem. Thus, to this optimization model, it is hard to obtain the optimization solution by classical optimization methods. An effective heuristic algorithm is given which is based on genetic algorithm and heuristic rules in the paper.
The proposed algorithm is segmented into two phases. In phase I, the optimal static solution for the first planning period is obtained by hybrid genetic algorithm. In phase II, based on the above optimal solution, the optimal solutions for the second and third planning period can be acquired by heuristic rules.

## (1) the description of heuristic rule

In the following discussion, $K_{o}(t)$ and $K_{C}(t)$ stand for the set of logistics nodes that are open and closed in period t respectively. $Z\left(K_{o}(t)\right)$ denotes the optimal objective function value for the static problem of DMLNLP in period t , with $K_{o}(t)$ being the set of open facilities in the optimal static solution.

Let $Z\left(\nabla_{j}^{t}\right), Z\left(\perp_{j}^{t}\right)_{\text {be the sum of transport costs and operator costs in the objective function value (i.e. the sum of } 1 \text { TC }}$ and OC in the objective function) before the logistics node i expanding and after expanding in period t , respectively.

Let $D D_{j}(t), D O_{j}(t)$ and $D E_{j}(t)$ be the change value of the sum of transport costs and operator costs in the objective function due to logistics node j opening ,closing and expanding in period $t$, respectively.

## heuristic rules

(1) opening rule: if the savings in opening logistics node $j$ at time $t$ is more than additional investment with opening, it is rational to open logistics node $j$. It can be expressed as:

$$
\begin{equation*}
D D_{j}(t)=\left[Z\left(K_{o}(t)+j\right)-Z\left(K_{0}(t)\right)\right]>F_{j} \quad \forall j \in K_{C}(t) \tag{14}
\end{equation*}
$$

(2) closing rule: if the savings in closing logistics node $j$ at time $t$ is more than additional costs of transporting and operating with closing, it is rational to close logistics node j . It can be expressed as:

$$
\begin{equation*}
D O_{j}(t)=Z\left(K_{o}(t)\right)-Z\left(K_{0}(t)-j\right)<S_{j}^{t} \quad \forall j \in K_{o}(t) \tag{15}
\end{equation*}
$$

(3) expanding rule: if the savings in expanding logistics node $j$ at time $t$ is more than extra costs with closing, it is rational to expand logistics node j . It can be expressed as:

$$
\begin{equation*}
D E_{j}(t)=Z\left(\perp_{j}^{t}\right)-Z\left(\nabla_{j}^{t}\right)>a_{j}^{t} \quad \forall j \in K_{0}(t) \tag{16}
\end{equation*}
$$

## (2) solution algorithm

Step 1: sorting by the capacity of logistics nodes and calculating the upper bound of the number of logistics nodes needed.

Step 2: Constructing the virtual network based on the above logistics nodes needed.
Step 3: Applying the hybrid genetic algorithm based on revised ford-fakon algorithm to obtain the static optima solution under $\mathrm{T}=1$ (i.e.in the first period planning), and denoting its optimal objective value $Z_{1}\left(n_{i}^{*}, n_{j}^{*}\right)$, where $n_{i}^{*}, n_{j}^{*}$ is the number of $\mathrm{LN}(\mathrm{I})$ nodes and $\mathrm{LN}(\mathrm{II})$ nodes needed opening respectively.

Step 4: loading the flow of the second planning period into the optimal network of the first planning period, if the capacity of network can be meet the flow demand completely, goto Setp8 ;otherwise goto Step 5.
Step 5: Estimating the logistics nodes closed to the customers without fully satisfied according the above expanding rule, and calculating the minimum costs of expanding for all unsatisfied customers, denoting the extra expanding $\operatorname{cost} Z_{2}(E)$.
Step 6: Estimating the logistics nodes closed to the customers without fully satisfied according the above opening rule, and calculating the minimum costs of opening for all unsatisfied customers, denoting the extra opening cost $Z_{2}(O)$.

Step 7: Comparing $Z_{2}(E)$ with $Z_{2}(O)$, if $Z_{2}(E)<Z_{2}(O)$, it is reasonable to expand; otherwise,
it should take the plan of opening. By this method, the optimal solution under $\mathrm{T}=2$ (i.e.in the first period planning) can be obtained. Go to Step9.
Step 8: Calculating and sorting ascend the ratio of the using of all logistics nodes opening of the optimal solution under $\mathrm{T}=1$, and closing the logistics nodes with less ratio of the using according to the above opening rule. By this method, the optimal solution in $\mathrm{T}=2$ (i.e.in the first period planning) can be obtained. Go to Step9.
Step 9: Loading the flow of the second planning period into the optimal network of the first planning period, and by imitating the operations of Step4-Setp8, the optimal network of the third planning period can be obtained.
Step 10: Getting the finally optimal dynamic solution.

## (3) Transformation of virtual network

## Insert Figure 1 here

As Fig. 1 shown, if there are $m$ candidate nodes of $L N(I)$, $n$ nodes of $L N(I I)$ and $p$ customer zones, a virtual network can be constructed by adding a original node $s$ and destination node $t$.
Denoting $I=\{1,2, \cdots, m\}, J=\{1,2, \cdots, n\}, M=\{1,2, \cdots, p\}$

$$
d_{i j}: \text { the distance of node } \mathrm{I} \text { and node } \mathrm{j}, \text { where } i, j \in I \cup J \cup M
$$

$$
c a p_{i j}: \text { the throughput limit of the arc } \mathrm{ij} \text { (from node } i \text { to } j \text { ) }
$$

In the above virtual network, there exist the following rules:
(1) $d_{s i}=0 ;$ cap $_{s i}=\infty ; \forall i \in I$
(2) $d_{i j}=c_{i j} ;$ cap $_{s i}=U_{i j} ; \forall i \in I, j \in J$ where $\mathrm{C}_{\mathrm{ij}}$ denotes the transport costs between node $i$ and $j, \mathrm{U}_{\mathrm{ij}}$ denotes the maximum of the design capacity of node $i$ and $j$.
(3) $d_{j k}=c_{j k} ;$ cap $_{s i}=U_{j k} ; \forall j \in J, K \in M$ where $\mathrm{C}_{\mathrm{jk}}$ denotes the transport costs between node j and $k, \mathrm{U}_{\mathrm{jk}}$ denotes the maximum between the design capacity of node $j$ and the demand of customer zone $k$.
(4) $d_{k t}=0 ;$ cap $_{k t}=\infty ; \forall k \in M$
(4) the description of coding and genetic operator $s$

It is very important on how to represent the solution of the investigating problem as chromosome and to design genetic operator. In general, the binary code is a good alternative. The representation of chromosome is denoted as $\left[u_{1}, u_{2}, \cdots u_{m} \mid v_{1}, v_{2}, \cdots, v_{n}\right]$.
It indicates that the candidate $\mathrm{LN}(\mathrm{I}) i$ will be opened if ui is equal to 1 and the candidate $\mathrm{LN}(\mathrm{I}) i$ will be opened if $\mathrm{v} j$ is equal to 1 .
Based on the revised fork-fankson algorithm, the whole network flow assignment can be obtained and the objective function value is used to calculate the fitness of the associated chromosome.
Crossover operator is applied to the method of partially matched crossover (PMC). In order to ensure the feasibility of the offspring chromosome, it is necessary to fulfill remedy strategy. Zhao (2001) has given a detail description on the remedy strategy. The inversion operator is adopted for mutation operator in this paper.

## 4. A Numerical example

Suppose a city logistics nodes system planning is made according to its intending 20 years logistics demand changes, consisting of 3 stages: stage 1 is from the first year to fifth year, stage 2 is from the sixth year to tenth year, and stage 3 is from the eleventh year to the twentieth year.
There are 6 potential LN (I) nodes (I), 22 LN (II) nodes (J) and 40 customer demand zones. Other input data is shown in the table1-5.
Insert Table 1 here
Insert Table 2 here
Insert Table 3 here
Insert Figure 2 here
The figure 2 shows the change curve of objective function in the evolvement of GA algorithm.
According to the heuristics rules, the optimal result of the second period ( $\mathrm{T}=2$ ) is shown in table 7 , and the optimal result of the third period ( $\mathrm{T}=3$ ) is shown in table 8.

Insert Table 7 here
Insert Table 8 here

## 5. Conclusions

In this paper, a dynamic logistics nodes layout optimal model is proposed to investigate the distribution network design problem with multi-period, multi-commodity and multiple logistics nodes An effective algorithm based on the hybrid genetic algorithm and heuristic rules is presented according to the characteristic of optimization problem. Finally, a numerical example is provided to validate the proposed model and solution algorithm. The findings indicate the following rules:
(1) The ratio of the distribution cost and the sum of fixed cost and handling cost will take great influence on the optimal configuration of logistics nodes. The logistics nodes opening become more if the ratio increases.
(2) The relative relation between unit expanding cost and open cost takes great effective on dynamic optimal solution. The measure of expanding is adopted when the supply capacity is deficiency, when the unit expanding cost is less than unit open cost.
(3) The genetic operator Pm influences on optimal solution and the speed of convergence while the PC will takes mild effective. The ideal parameters of the hybrid GA is as follows:
popsize $=30, \mathrm{Pc}=0.8, \mathrm{Pm}=0.2$, gen $=150$
