## Abstract

The paper presents numbers which were derived from  $4n$ -based series in a matrix table. The numbers agree precisely with the total number of valence electrons surrounding the respective skeletal elements. The series approach focuses mainly on the number of skeletal elements and their respective number of valence electron content regardless of the origin of the electrons and the type of skeletal elements. For instance, any 6 skeletal elements of transition metal carbonyls surrounded by 86 valence electrons coded as (6,86), series  $S = 14n+2$  normally adopt an octahedral geometry whereas (6,26) series  $S = 4n+2$  for main group elements also tend to adopt an octahedral shape. The transition metal carbonyl cluster series were extensively covered in our previous articles. This paper demonstrates that the main group fragments, clusters and molecules which we normally explain by terms such as valency, valence electrons and octet rule also obey the  $4n$ -based series. The fragments, molecules and clusters of the main group elements correspond well to those of respective transition metal clusters especially the carbonyls if the masking electrons are removed from them. Hence, the series approach is a qualitative method that acts as a unifier of some transition metal clusters with some main group elements clusters.

**Keywords:** unifying cluster series, fragments, Isolobal fragments and series, valence electron content, valence matrix table, skeletal elements, octet and eighteen electron rules,  $k$ -values, multiple bonds, coding system, counting bonds using series

## 1. Introduction

The discovery of Isolobal principle was a milestone in the history of chemical sciences (Hoffmann, 1982). The principle ably links the concepts of organic, inorganic and organometallic chemistry (Hoffmann, 1982) by using chemical fragments. The fragments are extremely useful in explaining numerous carbonyl and borane shapes of clusters which have attracted the attention of scientists for many years (Lipscomb, 1963, Wade, 1971, 1976, Rudolph, 1976, Pauling, 1977, Jensen, 1978, Cotton, et al, 1980, Mingos, 1972, 1984, Douglas, et al, 1994, King, 2002, Jemmis, 2001a, 2001b, 2002, 2003, 2005, 2006, 2008, Bowen, et, al, 2007, King, et al, 2009, Welch, 2013). It was recently discovered that transition metal carbonyl clusters could readily be categorized using a matrix table (Kiremire, 2016a, 2016b) derived from  $14n$ -based series. What is interesting is that the valence electron content of a given carbonyl cluster, correspond precisely with a number that is found in the matrix table or its extension. For instance, the set of numbers (6, 86) represents six skeletal atoms of a cluster surrounded by a total of 86 valence electrons from the skeletal elements, cluster ligands and the charge if present. As we know, there is a wide range of clusters that that qualify for this code including  $M_6(CO)_{16}$ ,  $M = Co, Rh$  and  $Ir$ ;  $Os_6(CO)_{18}^{2-}$ ,  $Ru_6(C)(CO)_{17}$ , and  $Co_6(CO)_{15}^{2-}$ . Using the code notation (6, 86), it becomes easy to categorize the clusters by first removing the 'backbone electrons' of the series,  $6 \times 14 = 84$  from the total 86. The remaining 2 electrons are added for balancing the electron valence content. This can be formulated as  $S = 14n+2 = 86$  where  $n = 6$ . This set of numbers represents CLOSO series. Furthermore, a carbonyl cluster of 6 skeletal atoms surrounded by 86 valence electrons normally adopt an octahedral shape ( $O_h$ ) (Cotton and Wilkinson, 1980). It has been established that the carbonyl clusters follow the  $14n \pm q$  series while those of the main group elements follow the parallel series  $4n \pm q$  where  $q$  is an even integer (Kiremire, 2015). In the previous work, emphasis was placed mainly on carbonyl clusters. In this paper, the focus will be placed mainly on clusters of the main group elements covering the range of small to large clusters. An attempt will be made to correlate them with the transition metal carbonyls where necessary.

## 2. Results and Discussion

### Derivation of Numbers in the Matrix Table 1.

Since use of series to categorize clusters and fragments is not well known, it is important to explain briefly their origins and applications. It was recently found that categorization of carbonyl clusters is readily done using  $14n$ -based series. A sample of the series is represented in the matrix form shown in Table 1. Let us consider the series  $S = 14n+0$ , when  $n = 1$ ,  $S$  value is 14, when  $n = 2$ ,  $S = 14+2 = 16$ ;  $n = 3$ , and  $S = 14n+4 = 18$ , and  $n = 4$ ,  $S = 14n+6 = 20$  and so on. These numbers are given in first row of Table 1. The numbers of second row ( $n = 2$ ) of the Table and other rows are generated similarly. The hypothetical numbers in Table 1 have been derived from cluster series covering the range  $S = 14n-2$  to  $14n+12$ . For transition metal carbonyl series, most non-capped clusters lie within the series  $S = 14n+2$  (CLOSO),  $14n+4$  (NIDO),  $14n+6$  (ARACHNO),  $14n+8$  (HYPHO), and  $14n+10$  (KLAPO). Although the capping range stops at  $S = 14n-12$ , a large number of palladium carbonyls such as  $\text{Pd}_{23}(\text{CO})_{20}\text{L}_{10}$  ( $\text{L} = \text{PMe}_2\text{Ph}$ ),  $S = 14n-32$ ,  $\text{C}^{17}\text{C}[\text{M}-6]$  and  $\text{Pd}_{38}(\text{CO})_{28}\text{L}_{12}$ ,  $S = 14n-52$ ,  $\text{C}^{27}\text{C}[\text{M}-11]$  fall in the range of cluster series far below  $S = 14n-12$  (Kiremire, 2015, 2016). The corresponding numerical numbers based upon  $4n$  series for main group elements is shown in Table 2 which is the counterpart of Table 1 for transition metal carbonyl clusters. Table 3 gives a few selected examples of metal carbonyl complexes which belong to different family members (family branches) of the 'clan series'  $S = 14n+2$  (CLOSO),  $14n+4$  (NIDO) and  $14n+6$  (ARACHNO). Table 4 is the counterpart of Table 3 and gives a wide range of selected fragments of different families of the clan series  $S = 4n+0$  (MONO-CAPPED),  $4n+2$  (CLOSO),  $4n+4$  (NIDO),  $4n+6$  (ARACHNO) up to  $S = 4n+10$ . Table 4 covers simple two skeletal element clusters such as  $\text{C}_2\text{CN}^+$  to more complex seven skeletal element clusters such as  $\text{As}_7^{3-}$  (Zintl ion) and  $\text{Sb}_7^{3-}$ . A comparison between  $14n+4$  and  $4n+4$  for  $n$  values 1 to 10 giving selected example of each  $n$ -value to underpin the isolobal corresponding relationship between family members for transition metal fragments and main group elements. This is given in Table 5. The table also indicates that fragments which correspond to similar families have the same  $k$  values. For instance,  $\text{Rh}_2(\text{Cp})_2(\text{CO})_2$  ( $S = 14n+4$ ,  $k = 2$ ) and  $\text{C}_2\text{H}_4$  ( $S = 4n+4$ ,  $k = 2$ ). This means we have a  $\text{Rh}=\text{Rh}$  double bond in the former and another double bond in the later  $\text{C}=\text{C}$  in the latter. This study clearly indicates that the compounds and fragments of the main group elements tend to obey the law of series based upon  $4n$  skeletal backbone while the transition metal clusters especially the carbonyl series obey the law of series based upon  $14n$  skeletal backbone.

### The 18-Electron Rule and the Cluster Series Trees.

The 18 electron rule which is extremely useful and has been widely used (Tolman, 1972; Jensen 2005) as can be seen from Table 1 belongs to the series  $S = 14n+4$  (NIDO). The 18 valence electron content occurs when  $n = 1$  is inserted into the formula  $S = 14n+4$ . This means that in this case, each cluster fragment has one skeletal element surrounded by a total of 18 valence electrons. This figure of 18 is just one slot or box in the first row ( $n = 1$ ) in Table 1. A large number of transition metal complexes especially carbonyls fall into this box numbered 18. These include among others,  $\text{M}(\text{CO})_5$ ,  $\text{M} = \text{Fe, Ru, Os}$ ;  $\text{Ni}(\text{CO})_4, \text{Cr}(\text{C}_6\text{H}_6)_2, \text{M}(\text{C}_5\text{H}_5)_2, \text{Fe, Ru, Os}$ ;  $\text{M}(\text{CO})_6, \text{M} = \text{Cr, Mo, W}, (\text{C}_4\text{H}_4)\text{Fe}(\text{CO})_3, \text{V}(\text{CO})_6^-, \text{Mn}(\text{CO})_6^+, \text{Fe}(\text{CO})_4^{2-}, (\text{Cp})_2\text{Ti}(\text{CO})_2, \text{Mn}(\text{CO})_6^+, \text{Fe}(\text{CO})_4^{2-}, (\text{Cp})_2\text{Ti}(\text{CO})_2, (\text{C}_4\text{H}_6)\text{Fe}(\text{CO})_3, (\text{C}_6\text{H}_6)\text{Cr}(\text{CO})_3, (\text{Cp})\text{Co}(\text{CO})_2, (\text{Cp})\text{V}(\text{CO})_4, \text{and } \text{M}(\text{NH}_3)_6^{3+}, \text{M} = \text{Co, Rh, Ir}$ . If we regard  $n = 1$  for  $S = 14n+4$  as a branch of a large tree whose base is  $S = 14n+4$ , and  $n = 2$  as a second branch and  $n = 3$  as a third branch, and so on, then we can have a good understanding what the series represent. We can regard the tree as representing a CLAN TREE of cluster series with branches representing families with individual clusters as family members of that branch. Hence, the above complexes may be regarded as members of the cluster family of the first branch ( $n = 1$ ) for the 'clan series'  $S = 14n+4$  (NIDO). Sketches of the cluster trees are shown below T-1 for  $S = 14n+4$ , T-2 for  $S = 14n+2$  and T-3 for  $S = 14n+6$ . More clan trees of other series can be designed in the similar manner to include series for main group elements in T-4 and T-5 as well as the selected families for bi-capped series T-6, mono-capped series T-7, closo series T-8, nido series T-9 and arachno series T-10. As an illustration of the origin of the clan tree of series, let us consider the NIDO series  $S = 14n+4$  (T-1). The numbers 18( $n=1$ ), 32( $n=2$ ), 46( $n=3$ ), 60( $n=4$ ) and 74( $n=5$ ) are simply extracted from the Matrix Table 1 under the column labeled  $S = 14n+4$ . The numerical values are simply obtained by substituting the value of  $n$  into the series formula  $S = 14n+4$ . The sequence of the numbers is such that from one number to the next, there is a difference of 14. This is clearly a result of the change in  $n$  value by one since the series formula  $S = 14n+4$  remains constant. The significance of these numbers can be illustrated by  $S = 14n+4 = 18$  when  $n = 1$ . The value  $S = 18$  for  $n = 1$  represents a large number of transition metal complexes which have one central metal atom (skeletal element) surrounded by a total of 18 valence electrons. THIS IS THE BASIS OF THE 18 ELECTRON RULE which was put forward by Langmuir (Langmuir, 1921). Examples of complexes which obey the 18 electron rule are many including  $\text{Fe}(\text{CO})_5, \text{Ni}(\text{CO})_4, \text{Fe}(\eta^5\text{-C}_5\text{H}_5)_2, \text{and } \text{Co}(\text{NH}_3)_6^{3+}$ . The selected numbers shown in other clan trees (T-2 to T-10) of series were also extracted from Table 1 in a similar manner.

### The Applications of Series to Predict Possible Shapes and Linkages of Molecules and Clusters

The carbonyl clusters of low nuclearity, there is a correlation between the  $k$ -value and the linkages or bonds. For

example,  $\text{Rh}_2(\text{Cp})_2(\text{CO})_2$ ,  $S = 14n+4 \equiv 4n+4$ ,  $k = 2n-2 = 2(2)-2 = 2$ . A sketch of the complex is shown in S-1 indicating the presence of a double bond. Similarly  $\text{Mo}_2(\text{Cp})_2(\text{CO})_4$ ,  $S = 14n+2 \equiv 4n+2$ ,  $k = 2n-1 = 2(2)-1 = 3$ . This means, the complex is expected to have an  $\text{Mo}\equiv\text{Mo}$  triple bond (Meissler, et al, 2014). A sketch of the triple bond is shown in S-2 as well as other multiple bonds shown in S-3 and S-4 for  $\text{Mo}(\text{Cp})(\text{CO})_2\text{GeR}$  and  $\text{Ga}_2\text{R}_2^{2-}$  (Robinson, et al, 1997, 1998). We can also predict the skeletal shape of a cluster based on the value of  $n$  and  $k$  value as presented in the cluster trees. For instance,  $k = 2$  for  $n = 2$  in T-1. This means two skeletal atoms are linked with a double bond as shown in S-1. For  $n = 2$  and  $k = 3$ , this gives us a triple bond as in S-2 while in T-3,  $k = 1$  for  $n = 2$  giving us a single bond as in  $\text{Mn}_2(\text{CO})_{10}$  complex. For the same series T-1 ( $14n+4$ ), when  $n = 4$ ,  $k = 6$ . The characteristic shape for this is a tetrahedral ( $T_d$ ) as sketched in S-5. For  $n = 5$  and  $k = 8$  for  $S = 4n+4$ , the characteristic shape is a square pyramid sketched in S-6 and  $k = 9$  for M-5 gives a trigonal bipyramid as a characteristic shape (S-7) for  $S = 14n+2$  closo series and finally for  $k = 11$  and  $n = 6$  for  $S = 14n+2$ , the characteristic shape is  $O_h$ (S-8).

#### Derivation of Cluster Formulas from Cluster Series Formula

The cluster series formula carries some important information. The formula gives us the valence electron content of a cluster formula in question. It also gives the cluster number  $k$  which is related to cluster linkages and for ordinary molecules the  $k$  value is the same as the number of bonds linking up the skeletal atoms. For instance  $k = 3$  for  $\text{N}_2$  means that the two nitrogen atoms are linked with a triple bond. Furthermore, a knowledge of the series can assist us derive the appropriate cluster formula of the fragment for a given number of skeletal atoms. Let us consider a specific example as an illustration. Let the series be  $S = 14n+6$  (ARACHNO) and  $n = 2$ . The figure [14] in the series formula represents the backbone fragment electrons of the series,  $n$  = the number of skeletal atoms in the formula and 6 = the excess 'determinant' electrons of the series after  $14n$ . In this particular case, 6 tells us we are dealing with ARACHNO series. If the determinant number was 2, we will be dealing with CLOSO series and so on. The following scheme (Scheme 1) summarizes how the appropriate carbonyl clusters of different transition metal atoms can be generated from the series formula  $S = 14n+6$  for  $n = 2$  for the generation of the  $\text{Mn}_2(\text{CO})_{10}$ ,  $\text{Fe}_2(\text{CO})_9$  and  $\text{Co}_2(\text{CO})_8$  carbonyls. In Scheme 2, it is demonstrated how the carbonyl clusters,  $\text{Fe}_2(\text{Cp})_2(\text{CO})_4$ ,  $\text{Rh}_4(\text{CO})_{12}$ ,  $\text{Rh}_6(\text{CO})_{16}$  and the main group element clusters  $\text{B}_6\text{H}_6^{2-}$ , and the hypothetical Zintl ion type of clusters  $\text{M}_6^{2-}$ ,  $\text{M} = \text{C}, \text{Si}, \text{Ge}, \text{Sn},$  and  $\text{Pb}$  can be derived from a series formula.

#### Keeping the Number of Skeletal Elements Constant and Varying the Number of Valence Electron Content

Let us consider keeping the number of skeletal elements constant and changing the number of valence electron around them. This is simply illustrated in Table 6. As indicated in Table 6, two skeletal elements have been selected. If the skeletal atoms are transition metals in carbonyl clusters are surrounded by 28 electrons ( $S = 14n+0$ ,  $n = 2$ ), then  $k = 2n-0 = 2(2)-0 = 4$ . The increase in valence electrons by 2 from 28 to 30 changes the series to  $S = 14n+2$  with  $k = 2n-1 = 2(2)-1 = 3$ . A good example for this is  $\text{Mo}_2(\text{Cp})_2(\text{CO})_4$  which has an  $\text{Mo}\equiv\text{Mo}$  triple bond (Meissler, et al, 2014). When the valence electrons are increased again by 2 to  $S = 32$  the series formula becomes  $S = 14n+4$  with  $k = 2n-2 = 2(2)-2 = 2$ . This means that the two skeletal atoms get linked up by a double bond. This is what is indeed observed in  $\text{Rh}_2(\text{Cp})_2(\text{CO})_2$  carbonyl cluster complex where a  $\text{Rh}=\text{Rh}$  bond is present (Meissler, et al, 2014). Further increase of the valence electrons by 2 the series formula becomes  $S = 14n+6$  and  $k = 2n-3 = 2(2)-3 = 1$ . Thus, the bond order has decreased further to 1. The linkage between the two skeletal atoms is one. This is what is observed in  $\text{Mn}_2(\text{CO})_{10}$  where  $\text{Mn}-\text{Mn}$  single bond is present (Meissler, et al, 2014). A similar variation in bond order is experienced in moving from  $\text{C}_2\text{H}_6$  ( $S = 4n+6 = 14$ ,  $k = 2n-3 = 2(2)-3 = 1$ ) where  $\text{C}-\text{C}$  single bond is known to  $\text{C}_2\text{H}_4$  ( $S = 4n+4 = 12$ ,  $k = 2n-2 = 2(2)-2 = 2$ ) where we get a  $\text{C}=\text{C}$  double bond. Further decrease in valence electrons by 2 to  $\text{C}_2\text{H}_2$  ( $S = 4n+2 = 10$ ,  $k = 2n-1 = 2(2)-1 = 3$ ) where we get a  $\text{C}\equiv\text{C}$  triple bond. Finally, when 2 more valence electrons are removed to produce  $\text{C}_2$  ( $S = 4n+0 = 12$ ,  $k = 2n-0 = 2(2)-0 = 0$ ) where we get a controversial  $\text{C}\equiv\text{C}$  quadruple bond (Shaik, et al, 2012). Therefore, according to the series approach, if the number of skeletal atoms are kept constant and the number of valence electrons is increased, the  $k$ -values or skeletal linkages are decreased and vice versa. In principle, according to the series analysis, if we were to add 2 more electrons to  $\text{Mn}_2(\text{CO})_{10}$  ( $S = 14n+6$ ,  $k = 1$ ), we would get  $[\text{Mn}_2(\text{CO})_{10}]^{2-}$ ,  $S = 14n+8$ ,  $k = 2n-4 = 2(2)-4 = 0$ . This implies that  $[\text{Mn}_2(\text{CO})_{10}]^{2-}$  is unstable and decomposes into  $2[\text{Mn}(\text{CO})_5]^-$  ions which belong to the series  $S = 14n+4$  that obeys the 18 electron rule. In the same way, adding 2 electrons to  $\text{C}_2\text{H}_6$  ( $S = 4n+6$ ,  $k = 2n-3 = 2(2)-3 = 1$ ) we would get  $[\text{C}_2\text{H}_6]^{2-}$  ( $S = 4n+8$ ,  $k = 2n-4 = 2(2)-4 = 0$ ). What this implies by having  $k = 0$ , is that the system  $[\text{C}_2\text{H}_6]^{2-}$  ( $k = 0$ ) is unstable and it decomposes to form  $2[\text{CH}_3]^-$  ions. These are equivalent to having 2  $\text{CH}_4$  molecules which obey the series  $S = 4n+4$  and this is consistent with the octet rule.

## SCHEME 2. MORE CONVERSION EXAMPLES

**3. Conclusion**

Just as in transition metal carbonyl clusters which form according to  $14n$ -based series, the elements of the main group periodic table form compounds, ions, fragments and clusters which follow the  $4n$ -based series. Then ( $n$ ) in the series formula represents the number of skeletal elements in a fragment. For the main group elements a carbon atom (C) or (BH) fragment are good building blocks and each fragment comprises of 4 valence electrons. In the case of transition metal carbonyl clusters the building block or skeletal backbone fragment comprises of 14 valence electrons. A series formula  $S = 14n + q$  or  $S = 4n + q$  may be regarded as representing many clusters, molecules and fragments. The numerical values corresponding to  $n = 1, 2, 3, 4$ , and so forth may be considered to be family cluster branches for  $S = 14n + q$  or  $4n + q$ . Thus, we may regard,  $S = 14n + q$  or  $4n + q$  as a 'cluster clan tree' out of which various cluster families emanate. We may regard a carbonyl cluster complex of specific number of skeletal elements and valence electrons to join its family members on any suitable branch corresponding to a particular family clan tree. Thus, the chemical fragments precisely belong to specific cluster families of specific clan tree series. The 18 electron rule ( $S = 14n + 4$ ,  $n = 1$ , NIDO CLAN TREE) or 16 electron rule ( $S = 14n + 2$ ,  $n = 1$ , CLOSO CLAN TREE) or octet rule ( $S = 4n + 4$ ,  $n = 1$ , NIDO CLAN TREE, MAIN GROUP ELEMENTS) are special cases of cluster families of specific clan trees. They may be considered to be the first families we encounter at the beginning of the clan trees of series. In summary, the transition metal complexes especially carbonyls have a tendency of forming clusters and fragments in accordance with  $14n$  series whereas the main group element clusters or compounds and fragments are formed according to  $4n$  series.

**Acknowledgements**

The author wishes to express gratitude to the University of Namibia for the provision of facilities and NAMSOV, Namibia for the financial support, Mrs Merab Kambamu Kiremire for her continued encouragement to write the articles and Mr. Philipus Hishimone for assisting in drawing the sketches of chemical structures.
